Received 25 November 2004

The status of RHIC theory and phenomenology is reviewed with an emphasis on the indications for the creation of a new deconfined state of matter. The critical role of high energy nuclear physics in the development of theoretical tools that address various aspects of the QCD many body dynamics is highlighted. The perspectives for studying nuclear matter under even more extreme conditions at the LHC and the overlap with high energy physics is discussed.

Keywords: relativistic heavy ions, soft hadrons and thermalization, perturbative QCD, coherent power corrections, non-Abelian energy loss

1. Introduction

Quantum Chromodynamics and asymptotic freedom¹ predict the existence of a new state of matter², the quark-gluon plasma (QGP), at exceedingly high temperatures and energy densities similar to the ones that characterized the first few microseconds after the Big Bang. The quest for such a deconfined state of QCD has led to the highly successful program at the Relativistic Heavy Ion Collider (RHIC) and will be an integral part of the program at the Large Hadron Collider (LHC). Recent theoretical developments have improved our understanding of the complex many-body dynamics in high energy nuclear collisions. Comparison between data and theory is suggestive of the creation of a deconfined state of QCD with energy density on the order of 100 times normal nuclear matter density. For a review of the RHIC experimental results see³.

2. Soft and Intermediate p_T Hadrons

An economical description of the bulk particle production in $A + A$ reactions can be achieved in the framework of the thermal model. All measured particle ratios at midrapidity from the $\sqrt{s_{NN}} = 130, 200$ GeV $Au + Au$ runs at RHIC are well reproduced with $T_f \approx T_c \simeq 175$ MeV and $\mu_B = 40, 30$ MeV, respectively⁴. Such approach, while instructive, does not carry information about the dynamical evolution prior to freeze-out. Constraining the initial conditions, relevant at the early

2 *Ivan Vitev*

stages of relativistic heavy ion collisions, requires the development and application of microscopic models.

Relativistic hydrodynamics. Differential particle distributions at low p_T can be calculated in the framework of relativistic hydrodynamics⁵, which assumes local thermal equilibrium and solves the energy-momentum and current conservation

$$\partial_\mu T^{\mu\nu}(x) = 0, \quad \partial_\mu j_i^\mu(x) = 0. \quad (1)$$

Additional constraints, necessary to determine the system Eq. (1), include, for example, ideal hydrodynamics and equation of state $p = p(\epsilon)$ or a boost invariant Bjorken model. Good description of the $p_T \leq 2 - 3$ GeV hadron spectra for π^\pm , K^\pm , $p(\bar{p})$, $\Lambda(\bar{\Lambda})$, Ω, \dots can be obtained. However, the elliptic flow v_2 of massive hadrons was shown to be much more sensitive to the choice of equation of state (EOS) with first order phase transition (preferred) versus hadronic EOS⁶. Traces of early partonic thermalization, as suggested by hydrodynamics, can also be found in the mean p_T fluctuations versus centrality⁷.

Recent hydrodynamic simulations have employed initial conditions motivated by gluon saturation phenomenology⁸. In $A + A$ reaction this approach alleviates the problem with the transverse energy and the parton number in such models. However, it leaves an open question for $p + A$ reactions where the hydrodynamic description is not applicable.

Parton Coalescence. Another microscopic approach to low and moderate p_T hadroproduction is the covariant Boltzmann transport⁹. The theory was shown to be applicable not only in $A + A$ but also in $p + A$ reactions¹⁰ and has provided a good description of the rapidity density of hadrons dN^{ch}/dy and their transverse momentum distributions. The output of a partonic transport can be incorporated in the coalescence/recombination models that convolute the quark Wigner functions with the meson and baryon wavefunctions¹¹. These predict scaling properties of the elliptic flow v_2 ¹²

$$v_2^M(p_T) = 2v_2^p(p_T/2), \quad v_2^B(p_T) = 3v_2^p(p_T/3) \quad (2)$$

at intermediate transverse momenta and enhanced baryon to meson ratios such as $p(\bar{p})/\pi^\pm$ and $\Lambda(\bar{\Lambda})/K^\mp$. The energy loss of quarks and gluons plays an important role in the generation of the elliptic flow at the partonic level¹³. It also suppresses the perturbative high p_T hadron production and thus extends the region of possible non-perturbative contribution for baryons¹⁴. Coalescence models have been used to calculate the expected charm meson transverse momentum distributions and the charm meson and baryon elliptic flow¹⁵.

3. The Perturbative QCD Factorization Approach

In the nuclear environment, modifications to the QCD factorization approach¹⁶ arise from the elastic, inelastic and coherent multiple scattering. These can be systematically incorporated in to the perturbative formalism¹⁷. For $\ell + A$, $p + A$

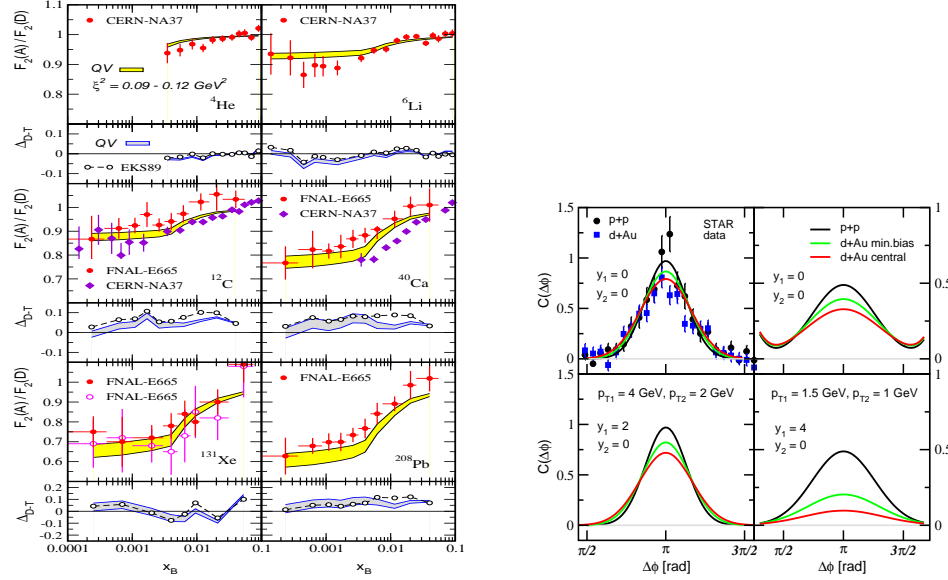

Fig. 1. Left panel from¹⁹: resummed QCD power corrections to nuclear shadowing in $\ell + A$, manifest in $F_2(A)/F_2(D)$. Right panel from²¹: modification of the away side correlation function $C(\Delta\phi)$ versus rapidity, centrality and p_T from higher twist.

and $A + A$ reactions their effect on experimental observables is summarized in Table 1. The relative importance of these distinct contributions in the different kinematic and density regimes is yet to be determined. Elastic scattering leads to a Cronin enhancement and a small broadening of the away side correlation function $C(\Delta\phi) = (1/N_{trig})dN^{h_1h_2}/d\Delta\phi$. These have been discussed in¹⁸.

Coherent power corrections. A class of corrections that can be naturally incorporated in the perturbative QCD factorization approach is associated with the power suppressed $\sim 1/Q^n$, $n \geq 1$ contributions. The higher twist terms are typically neglected in reactions with “elementary” nucleons for $Q^2 \geq 1 \text{ GeV}^2$. However, in the presence of nuclear matter such corrections can be enhanced by the large nuclear size $\sim A^{1/3}$.

The effective longitudinal interaction length probed by the virtual meson of

Table 1. Effect of elastic, inelastic and coherent multiple scattering on the transverse momentum distribution of hadrons in the perturbative regime.

Type of scattering	Transverse momentum dependence of the nuclear effect
<i>Elastic</i>	Suppression at low p_T , enhancement at moderate p_T , disappears at high p_T
<i>Inelastic</i>	Suppression at all p_T , weak p_T dependence, persists at high p_T
<i>Coherent</i>	Suppression at low p_T , disappears at high p_T

momentum q^μ is characterized by $1/xP$. If the momentum fraction of an active initial-state parton $x \ll x_c = 1/2m_N r_0 \sim 0.1$ with nucleon mass m_N and radius r_0 , it could cover several Lorentz contracted nucleons of longitudinal size $\sim 2r_0(m_N/P)$ in a large nucleus. Each of the soft interactions is characterized by a scale of power correction per nucleon $\xi^2 \approx \frac{3\pi\alpha_s(Q)}{8r_0^2} \langle p|\hat{F}^2|p \rangle$ with the matrix element $\langle p|\hat{F}^2|p \rangle = \frac{1}{2} \lim_{x \rightarrow 0} xG(x, Q^2)^{19}$. The multiple final state scattering of the struck quark generates a dynamical parton mass $m_{\text{dyn}}^2 = \xi^2(A^{1/3} - 1)$ and a consequent rescaling in the value of Bjorken- x ¹⁹:

$$x_B \rightarrow x_B + x_B \frac{M_q^2}{Q^2} + x_B \frac{\xi^2(A^{1/3} - 1)}{Q^2} = x_B \left(1 + \frac{M_q^2 + m_{\text{dyn}}^2}{Q^2} \right). \quad (3)$$

In Eq. (3) M_q is the physical mass of the quark in the final state.

In Ref. ²⁰ next-to-leading order global analysis of the nuclear parton distributions (nPDFs) was shown to strongly disfavor more than 5% gluon shadowing. This result also suggests that the observed attenuation in the structure functions is a result of multiple final state scattering since any dynamical mechanism will predict an effect twice as large for gluons when compared to quarks, $\xi^2 \rightarrow C_A/C_F \xi^2$.

Application to nuclear shadowing in the DIS structure function $F_2(A)$ is shown in the left panel of Fig. 1. The coherent nuclear enhanced power corrections in single and double inclusive hadron production in $p + A$ reactions have been evaluated in²¹. The apparent suppression of the away side correlation function $C(\Delta\phi) = (1/N_{\text{trig}})dN^{h_1 h_2}/d\Delta\phi$ is shown in the right hand side of Figure 1. As seen from Eq. (3), these modifications disappear at high p_T . It will be instructive to investigate the open charm production²² including resummed power corrections. Additional discussion of nuclear shadowing and antishadowing in the light front approach can be found in²³.

Non-Abelian energy loss. The most efficient mechanism that modifies the large transverse momentum hadroproduction in the presence of a hot and dense quark-gluon plasma is the medium induced gluon bremsstrahlung²⁴. It leads to strong suppression of high- p_T particles, known as jet quenching. Non-Abelian energy loss was also shown to be an effective attenuation mechanism in cold nuclear matter²⁵.

The qualitative behavior of the energy loss as a function of the density and the size of the system can be calculated using the GLV approach²⁷. To first order in opacity for static and 1+1D Bjorken expanding plasmas

$$\langle \Delta E \rangle \approx \begin{cases} \frac{9C_R\pi\alpha_s^3}{8} \rho^g \langle L \rangle^2 \ln \frac{2E}{\mu^2 \langle L \rangle}, & \text{static} \\ \frac{9C_R\pi\alpha_s^3}{4} \frac{1}{A_\perp} \frac{dN^g}{dy} \langle L \rangle \ln \frac{2E}{\mu^2 \langle L \rangle}, & 1+1D \end{cases}. \quad (4)$$

Application²⁶ of the QCD theory of energy loss to the single inclusive pion suppression and the attenuation of the away side dijet correlations is shown in Fig. 2. These persist, as shown by the calculation, to high p_T . For similar results see²⁸.

Better experimental techniques may reveal the redistribution of the lost jet energy²⁹ in low frequency modes $\geq \omega_{pl}$. The quenching of charm and beauty

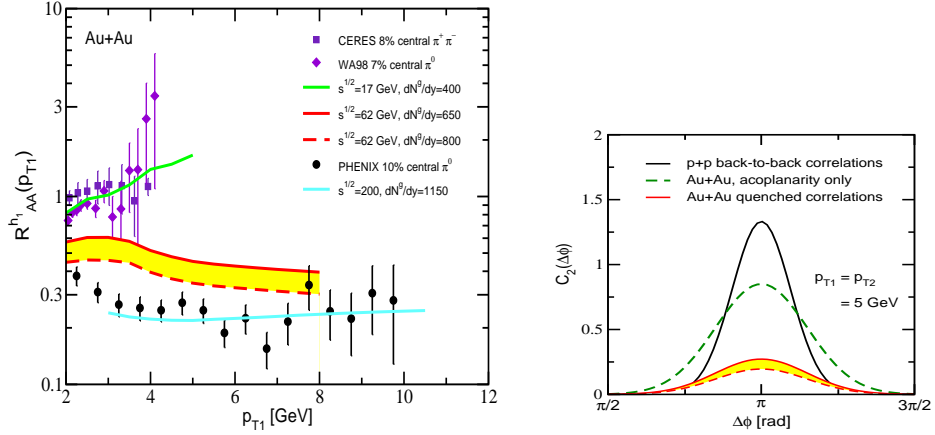

Fig. 2. Left panel from²⁶: nuclear modification factor $R_{AA}(p_T)$ at $\sqrt{s_{NN}} = 17, 62$ and 200 GeV. Right panel from²⁶: modification of the away side correlation function $C(\Delta\phi)$ from energy loss at high p_T .

mesons³⁰ will provide a physical scale, m_c and m_b , relative to which the parameters of the medium can be reliably extracted.

4. Conclusions

The complex dynamics of ultrarelativistic heavy ion reactions invites a variety of theoretical approaches, applicable in the different kinematic and density regimes, in the description of experimental observables. Consistent application of the models is required to better understand their strengths and limitation and to disentangle the distinct nuclear effects. At present, combined results from relativistic hydrodynamics and jet tomography suggest the creation of QGP at RHIC with initial energy density $\epsilon \simeq 15 - 20$ GeV/fm³. The interactions in the plasma, however, remain strong and are consistent with the lattice expectation of $\alpha_s \simeq 0.5$ ³¹.

The upcoming RHIC runs and the LHC program will ensure the dominance of high p_T and jet physics³² and will provide precision $A + A$ data at $\sqrt{s_{NN}} = 200 - 5500$ GeV³³. This opens new possibilities for studying photon and dilepton tagged jets, heavy flavor and multiparticle correlations. For cold nuclear matter, a low energy $p(d) + A$ run at RHIC will be a critical step in clarifying the relative importance of the nuclear effects summarized in Table 1.

Acknowledgments. I thank the organizers for the invitation to give this talk. This work is supported by the J.R. Oppenheimer Fellowship of the Los Alamos National Laboratory and by the US Department of Energy.
